2      B + A (B + A y0)
3      B + A (B + A (B + A y0))
4      (1 + A + A^2 + A^3) B + A^4 y0
5      (1 + A + A^2 + A^3 + A^4) B + A^5 y0
6      (1 + A + A^2 + A^3 + A^4 + A^5) B + A^6 y0
7      (1 + A + A^2 + A^3 + A^4 + A^5 + A^6) B + A^7 y0
8      (1 + A + A^2 + A^3 + A^4 + A^5 + A^6 + A^7) B + A^8 y0
9      (1 + A + A^2 + A^3 + A^4 + A^5 + A^6 + A^7 + A^8) B + A^9 y0
10     (1 + A + A^2 + A^3 + A^4 + A^5 + A^6 + A^7 + A^8 + A^9) B + A^10 y0
```

```
(1 + A + A^2 + A^3 + A^4 + A^5 + A^6 + A^7 + A^8 + A^9) * (1 - A) // Simplify
```

```
1 - A^10
```

$$\sum_{i=0}^k A^i$$

$$\frac{-1 + A^{1+k}}{-1 + A}$$

$$\left( \sum_{i=0}^k A^i \right) * (1 - A) \quad // \text{ Simplify}$$

$$1 - A^{1+k}$$

### ■ A more "difference equation" like style of notation

```

y[y0_, A_, B_, k_] :=
Module[{yy = y0, i = 0},
While [i < k,
i = i + 1;
yy = A * yy + B];
Return[yy] ]

y[100000, 1.05, -10000, 4]

78449.4

Table[{i, y[100000, 1.05, -10000, i]}, {i, 1, 15}]

{{1, 95000.}, {2, 89750.}, {3, 84237.5}, {4, 78449.4}, {5, 72371.8},
{6, 65990.4}, {7, 59290.}, {8, 52254.5}, {9, 44867.2}, {10, 37110.5},
{11, 28966.1}, {12, 20414.4}, {13, 11435.1}, {14, 2006.84}, {15, -7892.82}}

% // TableForm

1      95000.
2      89750.
3      84237.5
4      78449.4
5      72371.8
6      65990.4
7      59290.
8      52254.5
9      44867.2
10     37110.5
11     28966.1
12     20414.4
13     11435.1
14     2006.84
15     -7892.82

```

## ■ Representations / solutions in "closed form"

### Theorem (Annuity equation in closed form - AECF)

(cf. [DZ 1989], Satz 7.1, page 48)

The term  $y_k$  of the annuity equation

$$y_{k+1} = A \cdot y_k + B$$

can be expressed in the following way

$$(a) \quad y_k = (1 + A + A^2 + A^3 + A^4 + \dots + A^{k-1}) \cdot B + A^k \cdot y_0$$

If  $A \neq 1$  then

$$(a1) \quad y_k = \frac{A^k - 1}{A - 1} \cdot B + A^k \cdot y_0$$

If  $A = 1$  then

$$(a2) \quad y_k = k \cdot B + A^k \cdot y_0$$

**Exercise:** Prove the above theorem by formally applying (mathematical) induction.

### Corollary

(a1) The term  $y_k$  of the *geometric sequence*

$$y_{k+1} = A \cdot y_k$$

can be expressed in the following way

$$y_k = A^k \cdot y_0$$

(a2) The term  $y_k$  of the *arithmetic sequence*

$$y_{k+1} = y_k + B$$

can be expressed in the following way

$$y_k = k \cdot B + y_0$$

## ■ Some (philosophical) remarks on methodology and terminology

In the literature on difference equations the above theorem (in particular variant a1) is often expressed in a wording according to which the closed form representation  $y_k = \frac{A^k - 1}{A - 1} \cdot B + A^k \cdot y_0$  is the "solution" of the difference equation  $y_{k+1} = A \cdot y_k + B$ .

It is, however, debatable, in which sense this is the case and for what purposes the closed form representation is more adequate than the original (recursive) version (cf. J. Ziegenbalg: "Formula versus Algorithm"; paper presented at the the conference **The Origins of Algebra: From al-Khwarizmi to Descartes**, Universitat Pompeu Fabra (UPF) and Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, March 27-29, 2003)

Aspects subject to discussion are:

1. Computational efficiency
2. Cognitive efficiency
3. Historical aspects

The representations (a1) and (a2) in theorem AECF are often called *representations in closed form* or *solutions in closed form*. The terminology "closed form" suggests that these representations are non-recursive. But at a closer look this turns out to be only part of the truth, because in the evaluation, for instance, of a term like  $A^k$  recursion comes into the game, again.

In spite of all this, in the following text the standard terminology is adopted and in particular the term  $y_k = \frac{A^k-1}{A-1} \cdot B + A^k \cdot y_0$  will be called a "solution" of the difference equation  $y_{k+1} = A \cdot y_k + B$ .

Similarly, the term "solution" will also be used in this way for other (more general) difference equations.

## ■ Working with the *Mathematica* Package "Discrete Math"

The "add-on" package "Discrete Math" distributed with *Mathematica* contains the function `RSolve` (for "recurrence solve") by which solutions in closed form can conveniently be obtained for some types of recursive equations.

The next line shows how to load the `RSolve` function.

```
<< DiscreteMath`RSolve`
?RSolve
RSolve[eqn, a, n] solves a recurrence equation for the
function a, with independent variable n. RSolve[{eqn1, eqn2, ...},
{a1, a2, ...}, n] solves a list of recurrence equations. Mehr...
```

The next line shows an example of how to use the `RSolve` function.

```
RSolve[y[k + 1] == A * y[k] + B, y[k], k]
{{y[k] ->  $\frac{(-1 + A^k) B + (-1 + A) A^k C[1]}{-1 + A}$ }}
```

In the last expression `C[1]` is a constant which can be determined by adjusting the general form to initial values. The next line shows an evaluation, resulting in `y[0]`.

```
ReplaceAll[ $\frac{(-1 + A^k) B + (-1 + A) A^k C[1]}{-1 + A}$ , k -> 0]
C[1]
```

The same call in a different syntax:

```
 $\frac{(-1 + A^k) B + (-1 + A) A^k C[1]}{-1 + A}$  /. k -> 0
C[1]
```

Above, we used the definition  $y[0] = y_0$ . So the constant `C[1]` is just our initial value  $y_0$ .

In the next example, the initial conditions are specified within `RSolve`.

`RSolve[{y[k + 1] == A * y[k] + B, y[0] == y0}, y[k], k]`

$$\left\{ \left\{ y[k] \rightarrow \frac{(-1 + A^k) B + (-1 + A) A^k y_0}{-1 + A} \right\} \right\}$$

## ■ The generalized Fibonacci equation

### ■ A remark on the historical development

In his *Liber abaci* (1202), Leonardo of Pisa (called *Fibonacci*, ca. 1170 - 1250) formulated a problem giving rise to the following famous sequence of numbers now called the "Fibonacci" numbers:

1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, ...

Its most important property is that every member of the sequence is the sum of its two immediate predecessors (except for the initial values):

$$F_{k+2} = F_{k+1} + F_k$$

It took several centuries until J. P. M. Binet (1786-1856) finally presented the following formula for the Fibonacci numbers:

$$F_k = \frac{1}{\sqrt{5}} \left( \frac{1+\sqrt{5}}{2} \right)^k - \frac{1}{\sqrt{5}} \left( \frac{1-\sqrt{5}}{2} \right)^k$$

The formula nowadays is known as Binet's formula. We will now develop this formula within the framework of difference equations.

In case that the reader is doubtful that the formula is correct (which is perfectly plausible, regarding the complexity of the formula and in particular the embedded root expressions), here is a preliminary test:

$$\text{Table}\left[\text{N}\left[\frac{1}{\sqrt{5}} \left( \frac{1 + \sqrt{5}}{2} \right)^k - \frac{1}{\sqrt{5}} \left( \frac{1 - \sqrt{5}}{2} \right)^k\right], \{k, 1, 25\}\right]$$

{1., 1., 2., 3., 5., 8., 13., 21., 34., 55., 89., 144., 233., 377., 610.,  
987., 1597., 2584., 4181., 6765., 10946., 17711., 28657., 46368., 75025.}

### ■ Terminology

In this section we will consider the following linear difference equation of order 2 with constant coefficients and constant inhomogeneity

$$A_2 \cdot y_{k+2} + A_1 \cdot y_{k+1} + A_0 \cdot y_k = 0 \quad (\text{where } A_0, A_1 \text{ and } A_2 \text{ are fixed constants; } A_2 \neq 0)$$

Since  $A_2 \neq 0$  we can divide this equation by  $A_2$  and obtain the somewhat simpler but equivalent form

$$y_{k+2} + a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0 \quad (* \text{ GFE } *)$$

This equation clearly generalizes the Fibonacci equation; we will, therefore, call it the *generalized Fibonacci equation* (GFE) for short.

## ■ Applying standard methodology

Usually in mathematics (and elsewhere) it is more difficult to solve a generalized form of a specific problem than to solve the specific problem itself, for the solution of the generalized problem contains the solution of the specific problem. Sometimes, however, the solution of the more general problem turns out to be easier than the solution of the specific problem – thus supporting the dictum

*"be wise, generalize".*

Obtaining a closed form representation for the Fibonacci numbers is a striking illustration of this fact. It will turn out to be simpler and more natural to solve the generalized Fibonacci equation than the original (special) Fibonacci equation.

A general strategy in mathematical problem solving is to try to reduce a new, unknown situation to well-known cases. In this way, we will try to convert the generalized Fibonacci equation (of order 2) into two annuity equations (of order 1). If we succeed, we can hope combine the closed form representations of these annuity equations into a closed form representation of the generalized Fibonacci equation.

## ■ First attempt

The generalized Fibonacci equation might, for instance, be thought of as the "addition" of the following two first-order equations:

$$y_{k+2} + \frac{1}{2} a_1 \cdot y_{k+1} = 0$$

$$\frac{1}{2} a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0$$

**Exercise:** Convert each of these two first-order equations into the standard form for geometric sequences and show that they, in general, have no common solution (i.e. no common closed form representation).

## ■ Second attempt: Introducing new parameters for greater flexibility (in this case: introducing a "tuning" parameter)

Due to this result we have to handle the decomposition in a slightly more subtle way by introducing an extra parameter called  $t$  (for "tuning") in the following way.

$$y_{k+2} + (a_1 + t) \cdot y_{k+1} = 0$$

$$-t \cdot y_{k+1} + a_0 \cdot y_k = 0$$

Still, GFE can be thought of as being the sum of these first-order equations. If, by choosing a suitable "tuning" value for  $t$ , we can make these two first-order equations identical, then they will have the same closed form representations and we can try to combine their individual solutions into a solution for the generalized Fibonacci equation.

Written in the "standard" form for geometric sequences the last two first-order equations read

### ■ Tuning process - with the goal to make the two equations identical

$$y_{k+2} = -(a_1 + t) \cdot y_{k+1} \quad (* \text{ GS-1 } *)$$

$$y_{k+1} = \frac{a_0}{t} \cdot y_k \quad (* \text{ GS-2 } *)$$

These difference equations for geometric sequences are identical if their coefficients  $-(a_1 + t)$  and  $\frac{a_0}{t}$  are equal. (The "index-shift" by 1 is irrelevant, since the equations are valid for all values of  $k$ ).

A necessary condition for equality, hence, is

$$-(a_1 + t) = \frac{a_0}{t}$$

i.e.

$$t^2 + a_1 \cdot t + a_0 = 0$$

### ■ The characteristic polynomial

Thus, the above geometric sequences are identical if the "tuning" parameter  $t$  satisfies the so-called *characteristic equation* of (\* GFE \*):

$$x^2 + a_1 \cdot x + a_0 = 0$$

We finally obtain the tuning parameters

$$t_1 = \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2}$$

$$t_2 = \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2}$$

### ■ Solutions - by applying the results on geometric series

Thus, the geometric sequences adding up to (\* GFE \*) are

1. By using the root  $t_1$ :

$$y_{k+2} = -\left(a_1 + \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2}\right) \cdot y_{k+1}$$

$$y_{k+1} = \frac{a_0}{\frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2}} \cdot y_k$$

2. By using the root  $t_2$ :

$$y_{k+2} = -\left(a_1 + \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2}\right) \cdot y_{k+1}$$

$$y_{k+1} = \frac{a_0}{\frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2}} \cdot y_k$$

**Exercise:** Simplify these formulae.

## ■ Vieta's formulae

**Excursion:** Vieta's formulae

The tuning parameters  $t_1$  and  $t_2$ , being the roots of the quadratic equation

$$x^2 + a_1 \cdot x + a_0 = 0$$

must satisfy Vieta's equations:

$$t_1 + t_2 = -a_1 \quad \text{and} \quad t_1 \cdot t_2 = a_0$$

Thus, by substituting either  $t_1$  or  $t_2$  for  $t$  and applying Vieta's formulae we can rewrite (\* GS-1 \*) and (GS-2 \*) in the following way:

$$y_{k+2} = t_1 \cdot y_{k+1} \quad (* \text{GS-1.1} *)$$

$$y_{k+2} = t_2 \cdot y_{k+1} \quad (* \text{GS-1.2} *)$$

$$y_{k+1} = t_1 \cdot y_k \quad (* \text{GS-2.1} *)$$

$$y_{k+1} = t_2 \cdot y_k \quad (* \text{GS-2.2} *)$$

By pure combinatorics, substituting two roots into two equations formally gives four cases, but by algebra (Vieta) these melt down to two essentially different cases.

## ■ Results

### **Theorem (solutions of the generalized Fibonacci equation)**

(cf. [DZ 1989], Satz 13.1, page 90)

The generalized Fibonacci equation

$$y_{k+2} + a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0$$

has the following "solutions" (i.e. closed form representations):

$$(a1) \quad y_k = \left( \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2} \right)^k$$

and

$$(a2) \quad y_k = \left( \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2} \right)^k$$

Obtaining more solutions:

### **Theorem (combining solutions)**

If the sequences

$$(u_k)_{k=0, \dots, \infty} \quad \text{and} \quad (v_k)_{k=0, \dots, \infty}$$

are solutions of the generalized Fibonacci equation

$$y_{k+2} + a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0$$

then their "sum"

$$(a1) \quad (u_k)_{k=0,\dots,\infty} \oplus (v_k)_{k=0,\dots,\infty} := (u_k + v_k)_{k=0,\dots,\infty}$$

and for any real number  $C$  the "scalar multiple"

$$(a2) \quad C \odot (u_k)_{k=0,\dots,\infty} := (C \cdot u_k)_{k=0,\dots,\infty}$$

also are solutions of the generalized Fibonacci equation.

**Proof:** Exercise

Henceforth we will use the simpler operation symbols  $+$  and  $\cdot$  instead of  $\oplus$  and  $\odot$ .

### Corollary (linear combination of solutions):

If the sequences

$$(u_k)_{k=0,\dots,\infty} \quad \text{and} \quad (v_k)_{k=0,\dots,\infty}$$

are solutions of the generalized Fibonacci equation

$$y_{k+2} + a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0$$

then for any real numbers  $C_1$  and  $C_2$  the "linear combination"

$$C_1 \cdot (u_k)_{k=0,\dots,\infty} + C_2 \cdot (v_k)_{k=0,\dots,\infty}$$

also are solutions of the generalized Fibonacci equation.

### Corollary

The generalized Fibonacci equation

$$y_{k+2} + a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0$$

has the following "solutions" (i.e. closed form representations):

$$C_1 \cdot \left( \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2} \right)^k + C_2 \cdot \left( \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2} \right)^k \quad (* \text{ S-GFE } *)$$

where  $C_1$  and  $C_2$  are arbitrary real (or complex) numbers.

In other words: The set of all solutions of the generalized Fibonacci equation is a *vector space* over a suitable scalar field (usually the field the coefficients are taken from); cf. [DZ 1989], Satz 14.1, page 91.

Furthermore, it is not difficult to see that the dimension of this vector space is 2 and that, in case the solutions  $t_1$  and  $t_2$  of GFE's characteristic equation do not coincide, then the sequences  $(t_1)^k$  and  $(t_2)^k$  are a basis of this vector space.

## ■ Initial values

The above results were valid independent of any initial values  $y_0$  and  $y_1$  of the GFE. Let us now assume that the solution (\* S-GFE \*), additionally, is to satisfy these initial values. Then for  $k=0$  and  $k=1$  the following two linear equations will have to be satisfied by  $C_1$  and  $C_2$ :

### Corollary

The initial values of the generalized Fibonacci equation

$$y_{k+2} + a_1 \cdot y_{k+1} + a_0 \cdot y_k = 0$$

can be expressed in the following way:

$$C_1 \cdot \left( \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2} \right)^0 + C_2 \cdot \left( \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2} \right)^0 = y_0 \quad (* \text{ LE-1 } *)$$

$$C_1 \cdot \left( \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2} \right)^1 + C_2 \cdot \left( \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2} \right)^1 = y_1 \quad (* \text{ LE-2 } *)$$

i.e.

$$C_1 + C_2 = y_0$$

$$C_1 \cdot \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2} + C_2 \cdot \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2} = y_1$$

Notwithstanding the algebraic complexity of these equations, they are two simple linear equations in the two unknowns  $C_1$  and  $C_2$  which can be solved by straightforward algebraic procedures.

**Exercise:** Show that

$$C_1 = - \frac{-a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 - 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}$$

and

$$C_2 = - \frac{a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 + 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}$$

are solutions of (\* LE-1 \*) and (\* LE-2 \*).

## ■ Applying the results to the sequence of the standard Fibonacci numbers - Binet's formula

The sequence of the standard Fibonacci numbers, equivalently either starting with index 0 or index 1 is given by

$$\begin{array}{cccccccc} y_0 & y_1 & y_2 & y_3 & y_4 & y_5 & y_6 & y_7 & \dots \\ 0 & 1 & 1 & 2 & 3 & 5 & 8 & 13 & \dots \end{array}$$

Specializing from GFE, its parameters are:

$$a_1 = -1 \quad \text{and} \quad a_0 = -1.$$

Hence, the homogeneous equation

$$y_{k+2} - y_{k+1} - y_k = 0$$

has the "general" solution

$$y_k = C_1 \cdot \left( \frac{-a_1 + \sqrt{a_1^2 - 4a_0}}{2} \right)^k + C_2 \cdot \left( \frac{-a_1 - \sqrt{a_1^2 - 4a_0}}{2} \right)^k$$

i.e.

$$y_k = C_1 \cdot \left( \frac{1 + \sqrt{5}}{2} \right)^k + C_2 \cdot \left( \frac{1 - \sqrt{5}}{2} \right)^k$$

■ Putting it all together using *Mathematica's* "symbol manipulation" features

$$\text{Solve} \left[ \left\{ C_1 + C_2 == y_0, C_1 * \left( \frac{-a_1 + \sqrt{a_1^2 - 4 a_0}}{2} \right) + C_2 * \left( \frac{-a_1 - \sqrt{a_1^2 - 4 a_0}}{2} \right) == y_1 \right\}, \{C_1, C_2\} \right]$$

$$\left\{ \left\{ C_1 \rightarrow -\frac{-a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 - 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}, C_2 \rightarrow -\frac{a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 + 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}} \right\} \right\}$$

$$C_1 = -\frac{-a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 - 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}$$

$$-\frac{-a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 - 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}$$

$$C_1 = -\frac{-a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 - 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}} \quad /. \{a_0 \rightarrow -1, a_1 \rightarrow -1, y_0 \rightarrow 0, y_1 \rightarrow 1\}$$

$$\frac{1}{\sqrt{5}}$$

$$C_2 = -\frac{a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 + 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}$$

$$-\frac{a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 + 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}}$$

$$C_2 = -\frac{a_1 y_0 - \sqrt{-4 a_0 + a_1^2} y_0 + 2 y_1}{2 \sqrt{-4 a_0 + a_1^2}} \quad /. \{a_0 \rightarrow -1, a_1 \rightarrow -1, y_0 \rightarrow 0, y_1 \rightarrow 1\}$$

$$-\frac{1}{\sqrt{5}}$$

■ Binet's Formula

**Theorem (Binet)**

The Fibonacci equation

$$y_{k+2} = y_{k+1} + y_k$$

has the following "solution" (i.e. closed form representations):

$$y_k = \frac{1}{\sqrt{5}} \cdot \left( \frac{1+\sqrt{5}}{2} \right)^k - \frac{1}{\sqrt{5}} \cdot \left( \frac{1-\sqrt{5}}{2} \right)^k$$

Check

$$y_k = \frac{1}{\sqrt{5}} * \left( \frac{1 + \sqrt{5}}{2} \right)^k - \frac{1}{\sqrt{5}} * \left( \frac{1 - \sqrt{5}}{2} \right)^k$$

$$- \frac{\left( \frac{1}{2} (1 - \sqrt{5}) \right)^k}{\sqrt{5}} + \frac{\left( \frac{1}{2} (1 + \sqrt{5}) \right)^k}{\sqrt{5}}$$

$$\text{Table}\left[\left\{k, \frac{1}{\sqrt{5}} * \left( \frac{1 + \sqrt{5}}{2} \right)^k - \frac{1}{\sqrt{5}} * \left( \frac{1 - \sqrt{5}}{2} \right)^k\right\}, \{k, 0, 5\}\right]$$

$$\{0, 0\}, \left\{1, -\frac{1 - \sqrt{5}}{2\sqrt{5}} + \frac{1 + \sqrt{5}}{2\sqrt{5}}\right\},$$

$$\left\{2, -\frac{(1 - \sqrt{5})^2}{4\sqrt{5}} + \frac{(1 + \sqrt{5})^2}{4\sqrt{5}}\right\}, \left\{3, -\frac{(1 - \sqrt{5})^3}{8\sqrt{5}} + \frac{(1 + \sqrt{5})^3}{8\sqrt{5}}\right\},$$

$$\left\{4, -\frac{(1 - \sqrt{5})^4}{16\sqrt{5}} + \frac{(1 + \sqrt{5})^4}{16\sqrt{5}}\right\}, \left\{5, -\frac{(1 - \sqrt{5})^5}{32\sqrt{5}} + \frac{(1 + \sqrt{5})^5}{32\sqrt{5}}\right\}$$

$$\text{Table}\left[\left\{k, \frac{1}{\sqrt{5}} \left( \frac{1 + \sqrt{5}}{2} \right)^k - \frac{1}{\sqrt{5}} \left( \frac{1 - \sqrt{5}}{2} \right)^k\right\} // N\right], \{k, 0, 25\}$$

### ■ RSolve for GFE

```
Remove[y, y0, y1, a0, a1]
```

RSolving the GFE:

```

RSolve[{y[k+2] + a1*y[k+1] + a0*y[k] == 0, y[0] == y0, y[1] == y1}, y[k], k]

{{y[k] ->  $\frac{1}{2\sqrt{-4a0+a1^2}}$ 
  (  $\left( 2^{-k} (-a1 + \sqrt{-4a0+a1^2})^{1+k} + \left( -\frac{a1}{2} - \frac{1}{2}\sqrt{-4a0+a1^2} \right)^k (a1 + \sqrt{-4a0+a1^2}) \right) y0 +$ 
   $2^{1-k} \left( -(-a1 - \sqrt{-4a0+a1^2})^k + (-a1 + \sqrt{-4a0+a1^2})^k \right) (a1 y0 + y1) }}$ }}

```

RSolving the original Fibonacci equation:

```

RSolve[{y[k+2] - y[k+1] - y[k] == 0, y[0] == 0, y[1] == 1}, y[k], k]

{{y[k] ->  $-\frac{\left(\frac{1}{2}(1-\sqrt{5})\right)^k - \left(\frac{1}{2}(1+\sqrt{5})\right)^k}{\sqrt{5}}$ }}

```
